

# **House Price Prediction Capstone Project**

By Neeraj Walia

## Problem to solve

- Build a easy to use tool that homebuyers can use to search houses and predict home prices.
- Homeowners can use this to get an estimate price for their house before putting the house on sale.

# Introduction

- Home buyers need a tool that can easily narrow down their search selection for the house based on their **budget**, requirements and **location**.
- Predict/forecast home prices so home buyers can have an estimate and make an informed decision at the time of home purchase.
- Home owners can use this tool to estimate the market value of their house.

# Introduction

- I will be using advanced regression models to prediction:
  - Linear regression
  - Random forest regression.
- Web tool will be designed for easy to use and visual representation of data.

## Tools used

- Tableau for design the dashboard and hosting it for public use.
- Python for data analysis and predictive analytics.

# Data

- The dataset is available on kaggle website and its direct link is provided below.

<https://www.kaggle.com/c/house-prices-advanced-regression-techniques/data>

- The dataset contain residential homes information from Ames, Iowa. It contains 80 features (variables) representing every aspect of a house.
- There are two datasets train and test. Both has 1461 records of data. Train data has house price information. This data will be used to build the model.

NA
Pave

## New Columns

Alley_Grvl	Alley_Pave
1	0
0	0
0	1

# Categorical Data

- Convert text data to numerical by using One hot encoder from Sklearn.
- Test Dataset may not have all the data values as train dataset so after One hot encoder transformation, test dataset will not have same number of columns as train dataset.
- To avoid this issue, we will have column names of train data set in test and if data is not available in test will be given zero value.

```
one_hot_encoded_training_predictors = pd.get_dummies(df_train)
```

```
one_hot_encoded_test_predictors = pd.get_dummies(df_test)
```

```
final_train, final_test = one_hot_encoded_training_predictors.align(one_hot_encoded_test_predictors, join='left', axis=1)
```

# Correlation Matrix

# Feature Selection

- Run data through sklearn cross validation *cross\_val\_score* function.
- Data is split into k folds and (k-1) folds are used to train the data and one fold is to test. Repeat this process number of times and take the average of the target values.
- This process works in avoiding **overfitting**.

# Linear Regression

- Linear regression model is build on the processed train data.
- Cross validation `cross_val_score` function is used five times.

`cross_validation.cross_val_score(model_name,X,y,cv=5, scoring='mean_squared_error')`

- *Root mean square of Linear regression is 0.164*

# Random Forest Regression

- Random forest is an estimator that fits classifying decision tree on various samples of data and uses average to improve the predictive accuracy and control overfitting.
- Random forest regression model

```
rf = RandomForestRegressor(n_estimators = 1000, random_state = 42)rf.fit(X_train, y_train)
```

- Root mean square error of Random Forest Repressor is 0.142
- Prediction on test data is going to be done using this model as this has lower root mean square error value.

# Website
